Chapter 3.1A: Implement Evaluation Pipelines and Task Benchmarks

US General Service Administration
AI Community of Practice - March 2026

The Principles

EVALUATION PYRAMID

THREE FOUNDATIONAL PRINCIPLES

Shift-Left Testing

Find bugs early, fix them cheaply.
A bug in production costs 100x
more than in development.

Continuous Evaluation

Run on **every commit**
automatically

Balanced Metrics

Never optimize one
dimension blindly.
Accuracy gains are
worthless if latency triples.

Offline vs. Online Evaluation

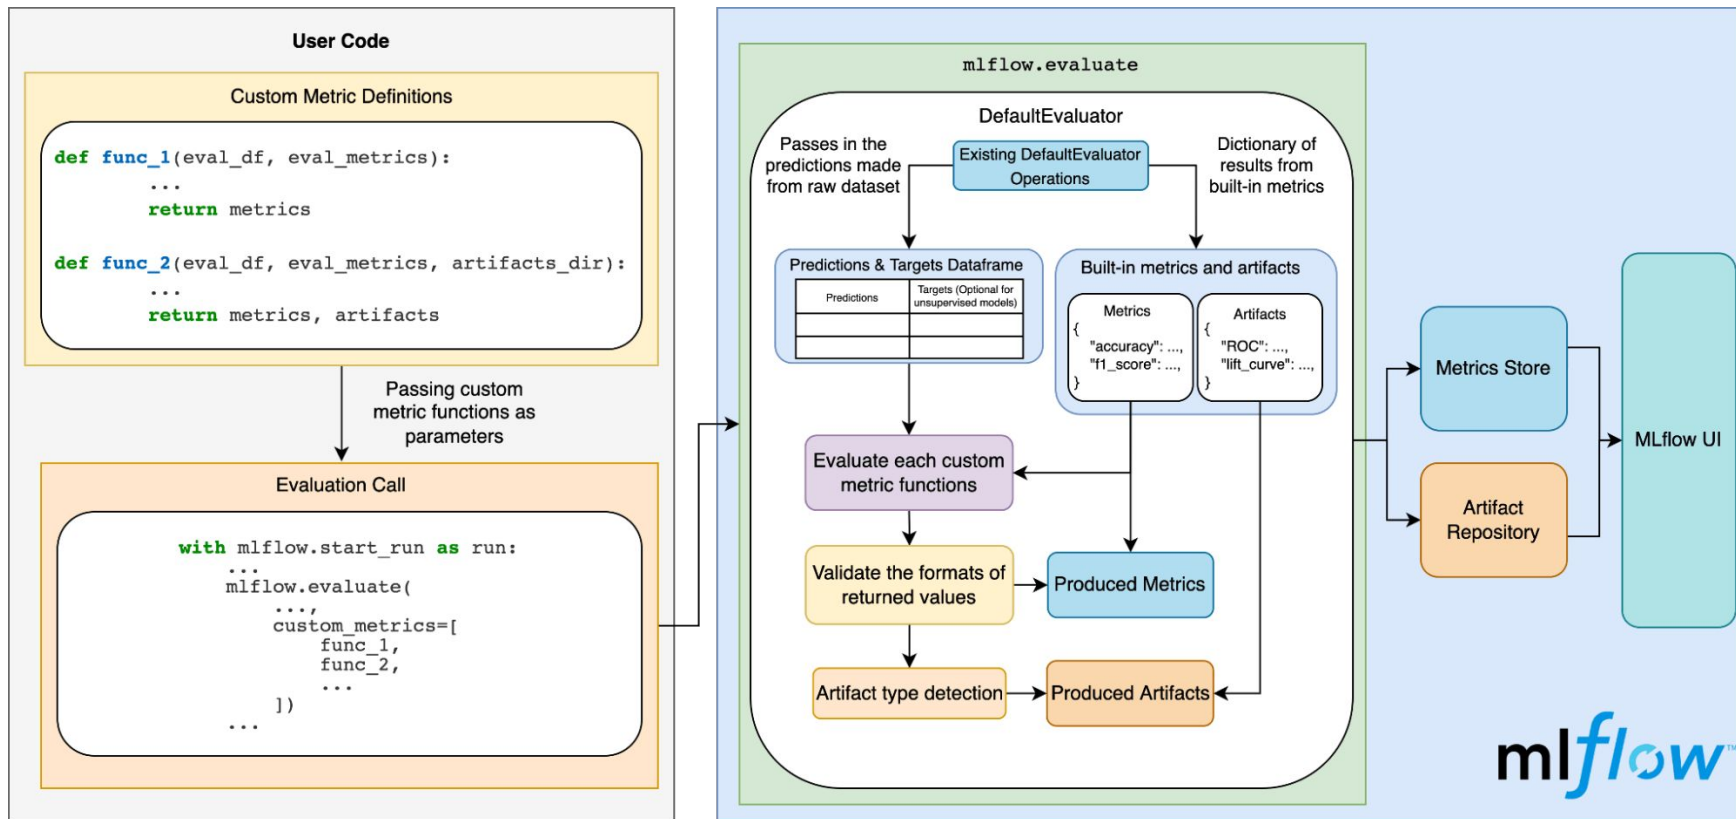

Evaluation Pipeline Architecture

Read more: <https://mlflow.org/blog/multiturn-evaluation/>

Building an Offline Pipeline with MLflow

Statistical Significance

- Raw metric changes can be random variation
- 87.0% to 87.5% accuracy might just be noise
- P-values quantify probability difference is real
- $p < 0.05$ means less than 5% chance of random fluke
- Confidence intervals show magnitude of improvement

A/B Testing -- Progressive Rollout Strategy

- Day 1: route 10% traffic to new agent version
- Day 2: scale to 25% if metrics hold steady
- Days 3-4: sustain and gather statistical power
- Day 5: confident move to 50% with evidence
- Day 7: full rollout to 100% after sustained success

Automatic Safeguards and Rollback

The Offline-to-Online Prediction Gap

Key Takeaways

- Task Success Rate is the primary agent reliability metric
 - Evaluation pyramid: unit tests, offline, staging, A/B testing
 - Shift-left testing reduces cost; continuous evaluation prevents regression
 - Statistical testing distinguishes improvement from noise
 - Always track multiple metrics to surface trade-offs
-
